Conclusions:

Insertion Sort is a proficient sorting algorithm when it comes to sorting a small amount of elements, but it's slower when sorting a large number of elements. At times (when the program is sorting less than 10k records), it sorts faster than Quicksort but the runtime increases significantly once the amount of record goes up. Since the original list of records wasn't ordered the runtime complexity of the algorithm was $O(n^2)$ time – the average case scenario.

Mergesort and Quicksort have very similar runtimes when both are compared to Insertion sort. Both can sort a small or large amount of elements in less than a second. The run time complexity of the two sorting methods was $O(n \log n)$ time because the records weren't ordered.

On a side note, in all three sort methods, the time it takes to sort the records by city names almost doubles when compared to sorting them by population. The city names are longer strings, so there were more characters to compare to each other which increased the runtime of the algorithm.
